

Rheumatic heart disease and pregnancy

IMPORTANT: Consider individual clinical circumstances. Read the full disclaimer at www.health.qld.gov.au/qcg

Background

Aspect	Consideration					
Aetiology	 Rheumatic heart disease (RHD) is caused by damage to the heart resulting from previous acute rheumatic fever (ARF)¹⁻³ ARF is caused by <i>Group A streptococcal</i> infection (throat and/or skin)^{3,4} ARF is associated with poor living conditions, overcrowding and socioeconomic deprivation^{3,4} 					
 Maintain awareness that high risk groups for ARF/RHD include women who⁶: Live in an ARF endemic setting Are Aboriginal and/or Torres Strait Islander, Maori and Pacific Islander peoples Are immigrants, or children of immigrants from low/middle income countries and with continuing high ARF and RHD prevalence Live in crowded households and/or are of lower socioeconomic status Are refugees or have spent time in refugee camps Have a personal history of ARF and are aged less than 40 years 						
Signs and symptoms of RHD (known or unknown cases)	 Maintain a high index of suspicion about women in high risk populations who present with⁵: Breathlessness, cough, wheeze or worsening fatigue Orthopnoea Significant reduction in exercise tolerance Syncope or presyncope Tachycardia Leg oedema Undiagnosed cardiac murmur 					
Classification	 ARF is classified as definite, probable or possible using Revised Jones Criteria⁵ There is no specific diagnostic laboratory test Diagnosis relies on clinical recognition of major and minor clinical manifestations RHD is classified as borderline or definite⁵ Diagnosis is based on echocardiographic features Lesion severity is classified as mild or none, moderate or severe 					
RHD Register	 ARF and RHD are notifiable diseases in Queensland⁶ The Queensland RHD Register and Control Program is a statewide patient register and recall system for ARF and RHD If known or new RHD, contact the Queensland RHD register (1300 135 854) and update with pregnancy status 					

Preconception

Aspect	Consideration					
Assessment	 Preconception care is key to optimising pregnancy and perinatal outcomes^{7,8} Identify at risk groups to target information sharing and assessment Historical diagnosis of ARF and/or RHD may have been missed If known RHD, refer to cardiology and obstetric medicine services for individualised counselling about: Risks of ARF/RHD and pregnancy Management of medications and anticoagulation where indicated Contraceptive options available until full counselling completed 					
Pregnancy not recommended	 Pregnancy is not recommended if⁷: Significant pulmonary arterial hypertension Severe symptomatic mitral stenosis (mitral valve area less than 1.0 cm²) Severe symptomatic aortic stenosis (aortic valve area less than 1.0 cm²) Severe left ventricular impairment (ejection fraction less than 30%) New York Heart Association (NYHA) class III/IV If pregnancy not recommended, facilitate: Multidisciplinary team review including maternal fetal medicine specialist Psychological and emotional support 					

Effective: March 2022 | Review: March 2027 | Doc No: MN22.40-1-V1-R27

Clinical Excellence Queensland

Clinical standards

Aspect	Consideration					
Care pathways	 Establish and promote local antenatal pathways for accessing: Echocardiography Face to face and virtual/telehealth specialist care (including cardiology, maternal fetal medicine and obstetric medicine) Structure care so it is woman centred, culturally safe, multidisciplinary, coordinated and community based wherever possible Promote continuity of care models and nurse navigator services where available Coordinate multiple appointments where possible to reduce travel burden and time away from community and family 					
Model of care	 Individualise care and consider⁵: Severity of RHD Co-morbidities Preference for birthing location Engagement with health services and adherence with recommended treatments Access to services Social, cultural and financial risk factors 					
Culturally safe care	 Promote local community based care that incorporates and respects cultural values (e.g. Birthing on Country or Birthing in Our Community)⁵ If woman identifies as Aboriginal and/or Torres Strait Islander, offer support from advanced health care workers and multicultural nurse navigators at entry point to service where available Refer to: Queensland Health: Aboriginal and Torres Strait Islander Patient care guideline⁹ Queensland Health: Making tracks towards closing the gap in health outcomes for Indigenous Queenslanders by 2033: Policy and accountability framework¹⁰ Queensland Clinical Guidelines: Standard care¹¹ Queensland Health: Making tracks together: Queensland's Aboriginal and Torres Strait Islander health equity framework¹² Migrant and Refugee Women's Health Partnership: Culturally responsive clinical practice: Working with people from migrant and refugee backgrounds¹³ 					

Risk assessment and stratification

Aspect	Consideration					
Context	 RHD in pregnancy is associated with higher rates of perinatal morbidity and mortality¹⁴ Early diagnosis and/or management offers best opportunity for optimal outcomes¹⁴ 					
Significant cardiac risk factors	 Prior cardiovascular event or symptoms before pregnancy (e.g. congestive cardiac failure, systemic embolism) Dyspnoea with minimal exertion or at rest (NYHA class III/IV) Requires immediate evaluation by cardiology/physician and/or intensive care team Atrial arrhythmias Left ventricular dysfunction Severe mitral regurgitation (MR) or aortic regurgitation (AR) Moderate or severe pulmonary hypertension⁸ Multiple or stenotic valvular lesions Mechanical prosthetic heart valve 					
Risk stratification	 Refer to Table: Risk categories and care pathways If late booking, or limited or no antenatal care, expedite cardiac review to enable risk assessment and stratification¹⁵ Maternal risk is based on a combination of history, current symptoms and echocardiography Multiple risk classification schema have been developed and these have been modified and adapted by various bodies and organisations^{7,16-18} Assessment of risk level requires expert clinical judgement in a multidisciplinary context Determine level of risk in consultation with multidisciplinary team If continuation of pregnancy not recommended due to severity of RHD, termination of pregnancy may be offered Refer to Queensland Clinical Guideline: Termination of pregnancy¹⁹ 					

Antenatal care

Aspect	Consideration
Unknown RHD	 First presentation of RHD may be during pregnancy Symptoms of RHD/ARF may be difficult to distinguish from normal pregnancy changes Take history for prior cardiac events (e.g. heart failure, arrythmias)⁵ Perform cardiovascular examination For high risk populations without known RHD, explore history for RHD (e.g. penicillin injections, previous echocardiograms) Maintain low threshold for echocardiography and cardiac referral in at-risk populations^{5,15}
Known RHD	 All routine antenatal assessments are indicated Perform cardiovascular examination including baseline electrocardiogram (ECG) and echocardiogram If secondary prophylaxis (antibiotics for prevention of recurrent ARF) is currently prescribed, continue during pregnancy⁵ Monitor for pre-eclampsia²⁰ Can exacerbate valvular heart disease and is associated with increased risk of heart failure Strongly recommend: Oral health assessment to decrease risk of infective endocarditis⁵ Early anaesthetic review Review and modify medications as required Surveillance for infection and ARF recurrence Decreased immune function increases susceptibility Wide variation in presentations in pregnancy Monitoring of fetal growth and wellbeing in the setting of a maternal cardiac condition
Mechanical and/or prosthetic heart valves	 Bioprosthetic valves are usually well tolerated in pregnancy²¹ Women with a mechanical heart valve (MHV) are at a high bleeding and embolic risk, and of poor maternal and perinatal outcomes compared to women with a bioprosthetic heart valve^{18,22}
Anticoagulation	 Is required for all women with MHVs Management is complex; liaise with or refer to an expert practitioner for management options May be required for atrial fibrillation or venous thromboembolism (VTE) prophylaxis
Cardiac review and place of birth	 If known RHD, arrange cardiology review as early as possible in pregnancy Refer to Table: Risk categories and care pathways for guidance on frequency of cardiac review and recommended place of birth Individualise birth plan (including place of birth) according to level of risk and in consultation with multidisciplinary team
Planning birth	 Vaginal birth preferred unless specific indications for caesarean birth⁵ Caesarean section is indicated if: Unplanned labour and warfarinised^{5,7} Severe heart failure, haemodynamic instability or pulmonary hypertension Induction of labour may be indicated: To allow optimisation of anticoagulation in fully anticoagulated women To facilitate access to specialist medical staff at the birth If deteriorating maternal cardiac function Refer to Queensland Clinical Guideline: <i>Induction of labour</i>²³

Intrapartum care

Aspect	Consideration					
Context	 Peripartum is potentially the highest risk period as⁵: Cardiac output increases as heart rate and blood pressure rise during labour Inability to increase cardiac output secondary to moderate/severe RHD may lead to pulmonary oedema Auto transfusion occurs from the release of caval compression and sustained uterine contraction immediately postpartum 					
General principles	 Individualise intensive and/or invasive monitoring according to severity of disease Neuraxial blockade may be beneficial Maintain clinical surveillance for signs of cardiovascular deterioration (e.g. tachycardia, dyspnoea, fatigue, oedema, cyanosis) Monitor fluid balance because of increased risk of pulmonary oedema Avoid excessive intravenous fluids Recommend continuous electronic fetal monitoring in labour Continuous oxygen saturation monitoring may be indicated Paediatric or neonatal teams for birth according to individual clinical circumstances 					
 Administer antibiotic prophylaxis according to obstetric indications, and local regimens (e.g. instrumental birth)^{5,7,24} Insufficient evidence to recommend additional antibiotic prophylaxis for end women with RHD, including those with prosthetic valves^{5,7,25} 						
Second stage	 As indicated by condition, consider: Shortening active phase of second stage (e.g. episiotomy, instrumental vaginal birth) Limiting active maternal pushing to reduce additional load on the cardiovascular system Pushing in left lateral, rather than supine, lessens cardiovascular changes and improves preload Avoid prolonged lithotomy positioning 					
Third stage	 Limited high quality evidence to guide management in women with cardiac disease²⁶ Balance management strategies against maternal risk and life threatening bleeding⁵ Recommend modified active management of third stage and prophylactic uterotonics: Oxytocin 10 units intramuscularly (IM) immediately following birth An oxytocin infusion can be given prophylactically or for treatment of postpartum haemorrhage To minimise cardiovascular disturbance, preferentially administer oxytocin slowly by infusion in small volumes of diluent (50–250 mL) in accordance with local protocol Avoid administering bolus intravenous doses of oxytocin²⁷ Avoid ergometrine and carboprost where possible⁵ Misoprostol and tranexamic acid are not contraindicated²⁸ 					
Moderate risk	 Labour and birth Notify anaesthetist at onset of labour (especially if anticoagulated) Establish intravenous (IV) access Close surveillance of haemodynamic status and fluid balance If required, administer vasoactive medication Recommend early neuraxial blockade to help minimise tachycardia⁵, limit pain and prevent hypertensive responses that may lead to heart failure If obstetric considerations allow, assisted vaginal birth (forceps or vacuum) preferred to caesarean section Post birth IV fluids to replace vaginal blood loss only Monitor in birthing suite, intensive care (ICU) or high dependency unit (HDU) for 12 hours or overnight Monitor pulse, blood pressure, oxygen saturations, blood loss and dyspnoea 					
High risk	 Labour and birth as for moderate risk and: Consider invasive monitoring (arterial line) for labour and birth, with critical care nursing support if managed in birthing suite Consider birth in operating room suite Regular multidisciplinary clinical assessment Post birth as for moderate risk and: Monitor in HDU/ICU for at least 12 hours (risk of pulmonary oedema) Strict fluid balance chart and indwelling catheter 					

Postpartum

Aspect	Consideration					
Clinical surveillance	 Routine postnatal observations and care according to clinical condition Signs and symptoms of RHD may appear for the first time postpartum If new onset postpartum dyspnoea or cough, investigate promptly Signs and symptoms of underlying cardiovascular disease may occur up to five months postpartum²⁹ 					
Breastfeeding	 Refer to Queensland Clinical Guideline: Establishing breastfeeding³⁰ Review safety of cardiac medications during lactation 					
Anticoagulation	 Management of anticoagulation for women with MHVs is complex³¹ Liaise with or refer to an expert practitioner for management options For other anticoagulation indications, discuss anticoagulation recommencement with multidisciplinary team Review safety of anticoagulant medications during lactation 					

Discharge planning

Aspect	Consideration						
Discharge planning	 Confirm next dose of secondary prophylaxis treatment¹⁵ (if applicable) Facilitate access to secondary prophylaxis if away from local community (e.g. if baby is in neonatal intensive care) Promote health literacy with discharge plan, consider interpreter as required Take into consideration if woman has had RHD, other children will often have an increased risk for ARF/RHD¹⁵ Referral to multicultural, rural or RHD nurse navigators where available 						
Conception counselling	 Counsel about the importance of contraception and the planning of future pregnancies Recommended interval between pregnancies is 24 months^{32,33} For girls and women with high risk cardiovascular disease and risk of unplanned pregnancy³⁴: Recommend long acting reversible contraceptives Intra-uterine contraceptive devices (IUCD) including levonorgestrel (Mirena®) and copper are safe Etonogestrel implant (e.g. Implanon®) Avoid oestrogen containing contraceptives as associated with elevated risk of thrombosis⁵ Barrier and 'natural' methods of contraception have unacceptable failure rates If further children not desired, explore tubal ligation 						
Follow up	 Follow-up cardiac review according to priority Arrange prior to discharge wherever possible High risk: referral to main cardiac clinic for management and possible cardiothoracic surgery Recommend Designated GP or primary care provider for home or centre based therapy and education following discharge Sharing information on treatment, medications, future management plans and conception planning with primary care providers/referring hospital within 48 hours of discharge¹⁵ 						

Risk categories and care pathways

If in doubt or borderline, refer to category with higher risk. Individualise risk stratification and actions according to clinical circumstances and consultation with experts.

Level	Risk category	General ⁵	Left ventricular impairment ^{5,7}	Valves ^{5,7,18}	Mitral stenosis ⁵	Aortic stenosis ⁵	Suggested actions ^{5,35}
IV	Extreme risk	Pulmonary arterial hypertension or NYHA class III/IV	Severe (EF < 30%)		Severe symptomatic (MVA < 1.0 cm ²)	Severe symptomatic (AVA < 1.0 cm ²)	 Preconception: advise against pregnancy If pregnant, continuation of may not be recommended Discussion about ToP may be required
	Very high	Severe symptomatic mitral regurgitation or aortic regurgitation		MV or AV disease with pulmonary hypertension	Severe (MVA < 1.5 cm²)		 Urgent cardiac review Cardiac review then monthly or more frequently as required Birth at CSCF level 5 or 6
III	High	Severe asymptomatic mitral regurgitation or aortic regurgitation	Moderate (EF 30–45%) ⁵	Mechanical heart valve	Moderate (MVA 1.5–2.0 cm²)	Severe asymptomatic (AVA < 1.0 cm ²)	 Cardiac review ASAP Cardiac review then 2nd monthly Birth at CSCF level 5 or 6
Ш	Moderate	Mild/suspected asymptomatic RHD and < 20 weeks at bookingModerate mitral regurgitation or aortic regurgitationNot mWHO III or IV	Mild (EF > 45%) without severe regurgitation or stenosis and good functional capacity	Bioprosthetic valves or Previous PBMV	Mild (MVA > 2.0 cm²)	Moderate (AVA 1.0–1.5 cm²)	 Cardiac review at next opportunity Cardiac review then each trimester (minimum) *Birth at CSCF level ≥ 4
1	 Mild or suspected RHD and ≥ 20 weeks at booking and BMI < 35 kg/m² and No significant co-morbidities History of ARF with no carditis, or mild MR or AR History of atrial arrhythmias in absence of significant valvular disease 				 Cardiac review including echocardiography and ECG Cardiac review then 1–2 times (minimum) Birth at CSCF level ≥ 3 		

^{*}Consider cultural significance for Aboriginal and Torres Strait Island women and families of birthing on homelands. CSCF level 3 may be appropriate in some circumstances in consultation with local experts, obstetric and cardiac specialists, and individualised risk assessment for each woman.

Abbreviations: > greater than; < less than; ≤ less than or equal to; AR aortic regurgitation; ARF acute rheumatic fever; ASAP: as soon as possible, AV aortic valve AVA aortic valve area; CSCF clinical services capability framework; ECG electrocardiogram; EF ejection fraction; MR mitral regurgitation, MV mitral valve, MVA mitral valve area; mWHO modified World Health Organization; NYHA New York Heart Association; PBMV percutaneous balloon mitral valvuloplasty; RHD rheumatic heart disease, ToP termination of pregnancy.
